

* Views:-

In RDBMS, a view is a virtual table created from the result of a query. Unlike physical tables, views do not store data themselves; instead, they provide a way to look at the data stored in one or more underlying tables. Views are especially useful for simplifying complex queries, enforcing security & presenting only the required data to the user. In the context of our Workout Planner project, views are created on top of Exercises & Available Equipments tables to provide meaningful insights for users & administrators.

* Types of views:-

There are several types of views supported in SQL, each serving different purposes:

1) Simple views (single-table views):

These are created from a single table & usually display a subset of its columns.

2) Updatable views:

These allow users to perform INSERT, UPDATE & DELETE operations through view, provided they follow certain restrictions.

3) Complex views (Multi-table views):

These are created using joins across multiple tables. They combine related data, which makes them useful for reporting & analysis.
